BACKGROUND

- Zanubrutinib is a potent, selective, and irreversible next-generation BTK inhibitor
- designed to maximize BTK occupancy and minimize inhibition of off-target kinases¹ Zanubrutinib has demonstrated a complete and sustained BTK occupancy in peripheral blood mononuclear cells and lymph nodes²
- Zanubrutinib has shown equipotency against BTK compared with ibrutinib.¹ Zanubrutinib has high selectivity for BTK and minimal off-target inhibition of TEC- and EGFR-family kinases¹
- Favorable drug interaction properties allow zanubrutinib to be co-administered with strong or moderate CYP3A inhibitors (eg, antifungals) at a reduced dose, plus proton pump inhibitors, acid-reducing agents, and antithrombotic agents^{3,4}

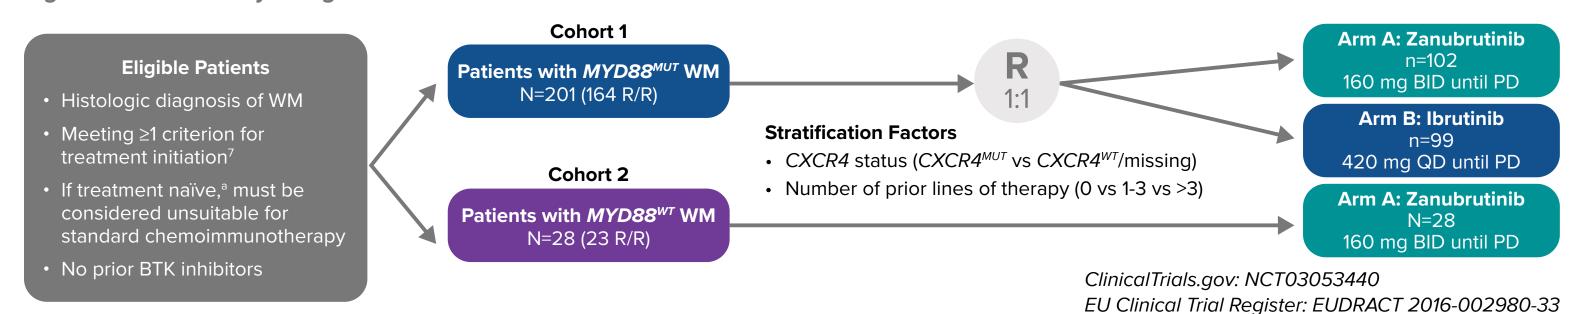

OBJECTIVES

- Primary Objective: To compare the efficacy of zanubrutinib vs ibrutinib in patients with activating MYD88^{MUT} WM; primary endpoint was the CR+VGPR rate
- Secondary Objectives: To further compare the efficacy, clinical benefit, and antilymphoma effects of zanubrutinib vs ibrutinib, and to evaluate safety and tolerability of zanubrutinib vs ibrutinib as measured by the incidence, timing, and severity of treatment-emergent AEs according to NCI CTCAE v4.03
- Exploratory Objectives: To evaluate the efficacy and safety of zanubrutinib in patients with MYD88^{WT} WM and the efficacy of zanubrutinib vs ibrutinib according to CXCR4 gene mutation in patients with MYD88^{MUT} WM

METHODS

ASPEN is an open-label, multicenter, randomized phase 3 study of zanubrutinib vs ibrutinib in patients with WM (Figure 1)

Figure 1: ASPEN Study Design: Zanubrutinib vs Ibrutinib in WM^{5,6}

^aUp to 20% of the overall population.

Cohort Assignments

- Bone marrow MYD88 and CXCR4 mutations were assessed centrally at study entry (NeoGenomics Laboratory, Aliso Viejo)^{8,9}
 - The MYD88^{MUT} assay includes a wild-type allele-blocking approach (LOD, 0.5%)^{7,8} and detects all mutations in the region encompassing amino acid Alanine²⁶⁰-Proline²⁷⁸, which includes the predominant mutation in WM, MYD88^{L265P} - Patients were assigned to cohort 1 (MYD88^{MUT}; randomized) or exploratory cohort 2 (MYD88^{WT} or MYD88 unknown; nonrandomized)

CXCR4 Mutation Detection

- Standard polymerase chain reaction/bidirectional Sanger sequencing assay to detect CXCR4WHIM mutation was performed at screening. Randomization in cohort 1 was stratified according to CXCR4 mutation status (CXCRWHIM vs CXCRWT/missing; LOD, 10%-15%)
- CXCR4 mutation status was assessed retrospectively by NGS using residual DNA samples or duplicate bone marrow biopsy sample (LOD, 0.25%)⁷⁻⁹

Response Assessments

Bold text indicates >10% difference between arms in cohort 1.

- Responses were assessed according to response criteria in the NCCN® WM guidelines and modified Owen criteria9 as assessed by the independent review committee (primary analysis)
- and by the investigator • Efficacy endpoints: response rates (CR+VGPR, major and overall responses), duration of response, time to response, time to next treatment, PFS, and OS

RESULTS

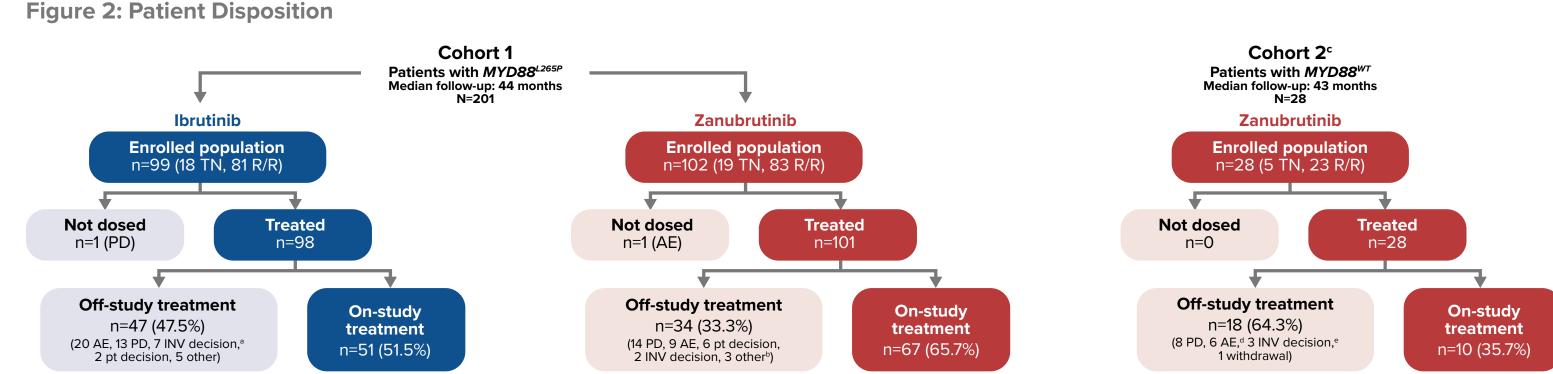

- Both arms in cohort 1 were balanced except for patients aged >75 years, patients with CXCR4^{MUT} by NGS, and patients with hemoglobin ≤110 g/L, which were higher on the zanubrutinib
- In cohort 2, patients aged >75 years were more frequent (42.9%)

Table 1: ASPEN: Baseline Demographics and Disease Characteristics

	Co	Cohort 2	
Characteristics	Ibrutinib (n=99)	Zanubrutinib (n=102)	Zanubrutinib (N=28)

High	44 (44.4)	47 (46.1)	12 (42.9)
Hemoglobin ≤110 g/L, n (%)	53 (53.5)	67 (65.7)	15 (53.6)
Baseline IgM (g/L, central lab), median (range)	34.2 (2.4-108.0)	31.8 (5.8-86.9)	28.5 (5.6-73.4)
Bone marrow involvement (%), median (range)	60 (0-90)	60 (0-90)	22.5 (0-50)
Extramedullary disease by investigator, n (%)	66 (66.7)	63 (61.8)	16 (57.1)

In cohort 1, 51 (51.5%) patients treated with ibrutinib and 67 (65.7%) patients treated with zanubrutinib remained in the study (Figure 2); main reasons for discontinuation were PD (n=14 and n=13) and AEs (n=9 and n=20) for zanubrutinib and ibrutinib, respectively

In cohort 2, 10 (35.7%) patients treated with zanubrutinib remained in the study; main reasons for discontinuation were progressive disease (n=8) and AEs (n=6)

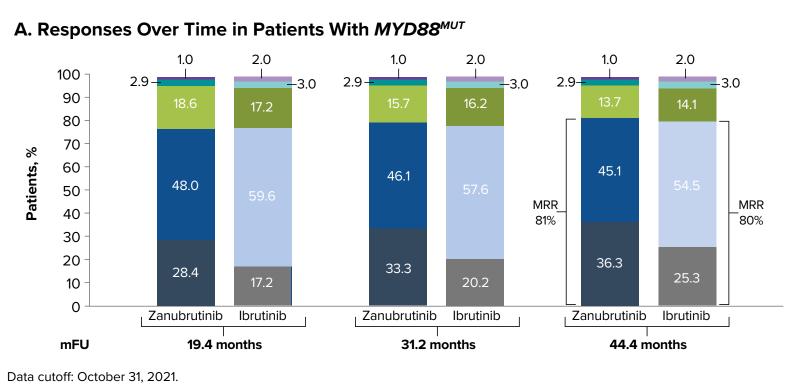

Data cutoff: October 31, 2021. ^aOne case related to COVID-19. ^bRadiotherapy for endometrial adenocarcinoma; patient started other anticancer therapy (rectal cancer); unwitnessed death (prior hospitalization for heart failure exacerbation but death not due to AE per site and no other information available). In cohort 2 (n=26 MYD88 mutation status unknown), the safety analysis set includes all 28 patients, and the efficacy analysis set includes 26 MYD88 mutation of 30 months. One case related to COVID-19. eINV decision: palliative care; mycobacterium infection required prolonged antibiotics; treatment for skin scleroderma.

Efficacy

- In cohort 1, the investigator-assessed cumulative response rate increased over time in both treatment arms (**Figure 3A**) No CRs were observed in cohort 1. Response rate of CR+VGPR was numerically higher at all time points with zanubrutinib compared with ibrutinib At 44.4 months median follow-up, CR+VGPR rates by investigator were 36.3%
- Median time to CR+VGPR was shorter for zanubrutinib: 6.7 months (range, 1.9-42.0) vs ibrutinib: 16.6 months (range, 2.0-49.9)
- Event-free rate for the duration of CR+VGPR at 24 months was higher for zanubrutinib: 90.6% (range, 73.6-96.9) vs ibrutinib: 79.3% (range, 53.5-91.8)
- Figure 3: Best Overall Response by Investigator Over Time

nonskin cancers

Long-Term Safety and Tolerability

- Zanubrutinib when compared with ibrutinib had fewer AEs leading to death, treatment discontinuation, and dose reduction (Table 3 and Figure 6)
- Most common AEs that led to discontinuation were cardiac disorder and infection (4% each) with ibrutinib vs second malignancy (4%) with zanubrutinib (**Table 3**) The profile of AEs of interest favored zanubrutinib compared with ibrutinib (Table 4, Table 5, and Figure 7)
- The prevalence of atrial fibrillation, hypertension, and bleeding were lower in the zanubrutinib arm at all time intervals
- Neutropenia occurred early, and prevalence decreased over time for patients receiving zanubrutinib - Prevalence of infection decreased over time and to a greater extent in the zanubrutinib arm
- A similar safety profile for zanubrutinib in cohort 1 was observed in cohort 2

Table 3: Overall Safety Summary

	Со	hort 1	Cohort 2

Data cutoff: October 31, 2021 ^aDescriptive purpose only, 2-sided P value. ^bEvents of the same preferred term that occurred within 1 day of the previous event. Patients with ongoing or new events in the interval are counted. ^cPercentage is based on N. ^dN is the number of patients who are on treatment in each time interval or who discontinued treatment but the time from first dose date +30 days, initiation of new anticancer therapy, end of study, death or cutoff date) is within the time interval.

CONCLUSIONS

- Zanubrutinib, with long-term follow-up, continued to demonstrate clinically meaningful efficacy in patients with WM
- Although not statistically significant at primary analysis, a consistent trend of deeper, earlier, and more durable responses (CR+VGPR compared with ibrutinib) was observed over time
 - Zanubrutinib provided faster and deeper responses in patients with CXCR4^{MUT}
 - PFS and OS continued to favor zanubrutinib treatment
- At median follow-up of nearly 4 years, 66% of patients remained on treatment with zanubrutinib versus 52% with ibrutinib - Responses to zanubrutinib in patients with $MYD88^{WT}$ (cohort 2) continued to deepen over time
- With longer follow-up, safety advantages of zanubrutinib remained consistent with less off-target activity compared
- with ibrutinib - Fewer AEs leading to treatment discontinuation, dose reductions, and deaths occurred in the zanubrutinib arm

ABBREVIATIONS

- Cumulative incidences of atrial fibrillation, diarrhea, hypertension, muscle spasm, and pneumonia were lower in patients receiving zanubrutinib - Despite a higher rate of neutropenia in the zanubrutinib arm, infection rates were similar and more patients in the
